The overall design choice of my interactive visualization was motivated by the idea to keep it simple yet expressive, while also displaying correlations between variables for each country. By hovering over each dot you can see each country to track that countries specific correlation between all of the variables. By merging all of the datasets into one with all of the variables I wanted, I was able to create an interactive scatter plot of the countries with a dropdown menu to explore correlation between gdp growth/age dependency ratio among other variables. Variables were chosen based on perceived correlation with specified variables as well incorporating other signaling methodologies such as multilinear regressions and looking over the f scores as well as individual P-values. Given all of this information I came to the conclusion that a scatterplot with a dropdown menu was the best course of action to answer my question, while staying relatively simple.
